APPENDIX I

THE PERMANENT SEED IDENTIFICATION CODE

By J. D. MATTHEWS

District Officer, Research Branch

(1). The new seed identification code system has been in operation for two years and increasing quantities of seed and plants bearing the new identity numbers are reaching nurseries and planting sites. The purpose of this note is to explain the objects of the new system, what it means and how it works. A list of the most important seed identity numbers is given for reference purposes and two maps illustrate the way the numbers are applied in Britain and the north-western American coastal region.

The Objects of the Code

(2). The permanent seed identification code is linked with the preparation of the Register of Seed Sources for both home collected and imported seed. This register contains details of classified seed sources in Britain and as time goes on will provide similar information for seed sources abroad. The register is being added to each year and it is desirable that it should be set out in a systematic manner using a seed identification code system which is (1) readily applicable to both home collected and imported seed (2) capable of expansion (3) readily indicates the origin of the seed or plants (4) consists entirely of numerals for convenience in keeping records.

ng-
the crop

(3). Seed used in British forestry both for large scale planting and for research purposes, comes from very widely scattered areas of the world and there are obvious advantages in using an existing system of numbers. The one selected is the Universal Decimal Classification, published by the British Standards Institution, which gives place numbers for the majority of the countries of the world. Figs. 3 and 4 illustrate the principle. The way in which the Universal Decimal Classification has been adapted for seed identification purposes is as follows:

The first digit within the brackets indicates Continents: e.g. (4) Europe.

The second digit within the brackets indicates larger countries and major Political Divisions: e.g. (42) England and Wales.

The third digit within the brackets indicates small countries and larger Provinces, Regions and Zones: e.g. (421) South-East England.

The fourth digit within the brackets indicates British Countries, French Departments, etc. and small States, Provinces and Zones: e.g. (4215) Sussex.

One or two digits outside the brackets indicate seed collection areas or classified seed sources which are considered to be important for practical purposes: e.g. (4215) 1 Slindon Wood, Slindon Park Estate.

Three digits outside the brackets indicate a Research Branch Collection made for experimental purposes only: e.g. (4215) 100 a single tree within Slindon Wood.

(4). When seed or plants from any seed source are distributed the seed identity code number is accompanied by two additional items of information which are also coded (1) the species name (coded as per SM.37) and (2) the crop year, i.e. the year in which the cones, fruit or seed have ripened. Thus, for example, Be. 58 (4215) 1 describes mast collected in the crop year 1958 from the Plus Stand of beech in Slindon Wood on the Slindon Park Estate and the full details of the boundaries of the stand and the quality of the trees can be found under (4215) 1 in the Register of Seed Sources.

Because the identity numbers are permanent all mast collected in any year from this seed source receive the same identity number, e.g. Be. 60 (4215) 1 and so on.

How the Code works in Practice

(5). The ultimate aim of the work being done on the many aspects of seed supplies in Britain is to ensure that all the seed used in British forestry comes from selected seed trees growing on specified areas. It will require some years of continuous effort to reach this goal and at present seed lots and the plants derived from them are of four kinds (1) General Seed Collections; (2) Collections from certain Specified Areas and Stands Classified as "Plus"; (3) Small Collections of Local Interest; (4) Research Branch Collections.

(6). General seed collections are those in which seed has been collected over considerable areas (e.g. Douglas fir from several seed collection points in the northern coastal region of Washington, U.S.A.) or from a number of stands which are of normal (i.e. average) quality or are unclassified (e.g. beech from several stands in eastern England). These collections are made to meet specific demands and the collection areas or the seed trees or both are more or less unselected. These general collections are bulked together in the two central seed stores at Alice Holt (for England and Wales) and Tulliallan (for Scotland) into large lots, mainly to reduce unnecessary record keeping and for practical working. The seed identity numbers used consist of two, three or four digits within the brackets, e.g. DF. 58 (7971) describes Douglas fir seed of

(3). Seed used in British forestry both for large scale planting and for research purposes, comes from very widely scattered areas of the world and there are obvious advantages in using an existing system of numbers. The one selected is the Universal Decimal Classification, published by the British Standards Institution, which gives place numbers for the majority of the countries of the world. Figs. 3 and 4 illustrate the principle. The way in which the Universal Decimal Classification has been adapted for seed identification purposes is as follows:

The first digit within the brackets indicates Continents: e.g. (4) Europe.

The second digit within the brackets indicates larger countries and major Political Divisions: e.g. (42) England and Wales.

The third digit within the brackets indicates small countries and larger Provinces, Regions and Zones: e.g. (421) South-East England.

The fourth digit within the brackets indicates British Countries, French Departments, etc. and small States, Provinces and Zones: e.g. (4215) Sussex.

One or two digits outside the brackets indicate seed collection areas or classified seed sources which are considered to be important for practical purposes: e.g. (4215) 1 Slindon Wood, Slindon Park Estate.

Three digits outside the brackets indicate a Research Branch Collection made for experimental purposes only: e.g. (4215) 100 a single tree within Slindon Wood.

(4). When seed or plants from any seed source are distributed the seed identity code number is accompanied by two additional items of information which are also coded (1) the species name (coded as per SM.37) and (2) the crop year, i.e. the year in which the cones, fruit or seed have ripened. Thus, for example, Be. 58 (4215) 1 describes mast collected in the crop year 1958 from the Plus Stand of beech in Slindon Wood on the Slindon Park Estate and the full details of the boundaries of the stand and the quality of the trees can be found under (4215) 1 in the Register of Seed Sources.

Because the identity numbers are permanent all mast collected in any year from this seed source receive the same identity number, e.g. Be. 60 (4215) 1 and so on.

The seed identity numbers used consist of two, three or four figures within the brackets, e.g. DF. 58 (7971) describes Douglas fir seed of the crop

year 1958 collected at two or more collection areas in the northern coastal region of Washington.

Similarly Be. 60 (425) would describe a general collection of beech mast made in eastern England in the crop year 1960.

(7). Collections from certain specified areas and stands classified as Plus are kept separate and given a distinguishing suffix number outside the brackets when the varieties associated with these areas or stands are known to be or show promise of being of practical value. For plus seed sources in Britain both the boundaries of the stand and the characteristics of the trees are known and described, e.g. Be. 58 (4215) 1 Slindon Wood, Slindon Park Estate; whereas a good variety from abroad may only be identified at present by means of a place name, e.g. DF. 58 (7974) 5 Darrington. Most forest services in Europe and elsewhere are now building up Registers of Seed Sources and the Manning seed firm also market "Bonded Maningseed" for which both the area of collection and quality of seed trees are guaranteed. This kind of seed lot will become more common as time goes on and seed collected from seed orchards will also receive the suffix numbers to distinguish the varieties permanently.

(8). Small collections of local interest are small quantities of seed (e.g. 2½ lb. of beech, 5 lb. of acorns or less than 1 lb. of conifer seed) collected from single trees or small groups of trees of local interest. It is not necessary to apply the full recording procedure to such seed lots unless there is a special reason for so doing.

(9). Research Branch Collections are generally small in size but are made for experimental purposes and so require accurate recording. Research Branch have devised an extension of the permanent identification code system and where necessary will use three digits outside the brackets to distinguish them. Silviculturist South has been allocated the numbers 100-499 and Silviculturist North will use 500-999. Thus PC. 58 (4122) 500 describes a collection of *Pinus contorta* seed made in the crop year 1958 by Silviculturist North in Experiment 12, Culbin Forest, Morayshire.

How the Code Numbers are Allocated

(10). Code numbers for imported seed are allocated at the Central Seed Store at Alice Holt which handles all imported seed.

Code numbers for home collected seed will eventually all be found in the Register of Seed Sources, copies of which are held by each Conservator. The Register for home seed sources is not yet complete because the survey on which the Register is based will not be completed until 1961. For the present, numbers for seed collected from *Unclassified* seed sources are allocated by the Conservator in whose Conservancy the seed has been collected—using the Region (three figure) identity numbers.

A Summary of Essential Information

(11). The permanent seed identification code system was devised to enable the comprehensive Register of Seed Sources to be compiled and added to over a long period of years.

(12). General seed collections receive identity numbers within the brackets; Collections from specified areas or stands classified as "plus" receive one or two distinguishing suffix numbers outside the brackets; Research Branch collections are further distinguished by three digits outside the brackets.
